Abstract

Modern agriculture and plant breeding must continuously meet the high and increasingly growing requirements of consumers and recipients. In this context, one of the conditions for effective management of any farm is access to quick and efficient diagnostics of plant pathogens, the result of which, together with the assessment of experts, provide breeders with tools to effectively reduce the occurrence of plant diseases. This paper presents information about biodiversity and spectrum of endophytic and phytopathogenic bacterial species identified in plant samples delivered to the Plant Disease Clinic in 2013–2019. During the tests, using the Biolog Gen III system, the species affiliation of the majority of detected bacterial strains found in plant tissues as an endophyte and not causing disease symptoms on plants was determined. These data were compiled and compared with the number of found identifications for a given species and data on the pathogenicity of bacterial species towards plants. In this way, valuable information for the scientific community was obtained about the species composition of the bacterial microbiome of the crop plants studied by us, which were confronted with available literature data. In the study, special attention was paid to tomato, which is the plant most often supplied for testing in the Plant Disease Clinic due to its economic importance.

Keywords: bacterial plant diseases, clinic, diagnostics, pathogen, tomato

Introduction

Bacterial pathogens cause significant losses in Polish agriculture (Pulawska *et al.* 2000; Pospieszny *et al.* 2007; Krawczyk *et al.* 2010, 2016; Mikiciński *et al.* 2010, 2016; Zwolińska *et al.* 2011, 2012, 2016; Iakimova *et al.* 2013; Kaluzna *et al.* 2014, 2016; Krawczyk and Borodynko-Filas 2020; Krawczyk and Łochyńska 2020) and around the world (Freeman and Pataky 2001; Esker and Nutter 2002; Coutinho and Venter 2009; Rapicavoli *et al.* 2018; Xin *et al.* 2018; Nabhan *et al.* 2019). Despite this fact, modern agriculture and plant breeding must meet the high and increasingly growing requirements of consumers and recipients. These requirements are dictated by strict phytosanitary regulations in force

concerning the marketing of plant products and by the expectations and awareness of consumers – the final recipients of plant-growing products. With long term usage of chemical crop protection, the products seem to reach the limits of their efficacy, beyond which no increase in yields is observed. Excessive usage of chemical crop protection products leads to adverse and often almost irreversible changes in the agricultural ecosystem. The introduction of integrated plant protection required by European Union regulations (from 2014) is expected to remedy these changes. These regulations aim to maximize the potential of biological plant protection while reducing the amount of chemical plant

protection products used. Increasing the biodiversity of agricultural agrosystems may decrease the number of observed plants showing disease symptoms caused by various pests and plant pathogens. This process has become particularly important in recent years. Climate change has resulted in the emergence of new diseases in Polish crops that previously had not posed a threat. In this context, effective management of any professional farm requires access to quick and efficient diagnostics of plant pathogens, which, together with the assessment of experts, can provide breeders with tools to effectively reduce the occurrence of plant diseases. In response to the demands of agriculture and society, the Plant Protection Clinic was established at the Institute of Plant Protection, in Poznań. The Clinic is the only accredited institution in Poland providing services in the field of identification of pathogens causing viral, bacterial and fungal diseases on agricultural, vegetable and ornamental plants, based on biological and molecular diagnostic methods. The laboratory was co-funded by European Union resources in March 2011, as part of the project “Modernization of laboratories to strengthen the innovation of research in the field of plant protection and economic activities” (WND-POIG.02.01.00-30-069/09-01). The laboratory is located in Poznań. Together with the Bank of Plant Pathogens it forms a separate department – “Plant Disease Clinic and Bank of Plant Pathogens” of the Institute of Plant Protection – National Research Institute. The role of the Clinic is to meet expectations of growers and use the experience and scientific resources of the institute to provide clients with high quality services of professional diagnostics of virological, bacteriological and mycological diseases of crop plants. As a result of the efforts and continuous improvement of the entire staff, the Clinic obtained accreditation by the Polish Centre of Accreditation (PCA), in the scope of our research methods. The Clinic obtained the credentials of an accredited laboratory on May 16, 2013 and currently uses accreditation number AB 1435.

The purpose of this article is to provide the reader with information about the biodiversity and scope of endophytic and phytopathogenic bacterial species identified in samples submitted to the Plant Disease Clinic (PDC) in the years 2013–2019. This study was aimed to provide the scientific community with insight into the scope of bacterial species identified in the tissues of various plant samples investigated in the Clinic.

According to the data of the Polish Central Statistical Office (SP 2018), Poland is the sixth-largest tomato producer in the European Union and nearly 70% of all cultivation is located in Greater Poland, Kuyavian-

-Pomeranian, Mazovian and Lublin voivodeships. As a result, the tomato (*Solanum lycopersicon*) is the most frequently tested crop in PDC.

Materials and Methods

In the PDC, the plant samples were registered, including the approximate location of their origin. The samples were then examined for the presence of bacteria, viruses and fungi pathogenic to plants. The technique of working with bacteria was as follows; plant fragments with disease symptoms were rinsed with distilled water to wash away residual of natural impurities. Then, the washed tissues were disinfected by immersion, for 1 min, in the following solutions: 10% hydrogen peroxide (H₂O₂), 70% ethyl alcohol (C₂H₅OH), and 5% sodium hypochlorite (NaOCl). Next, the disinfected plant parts were rinsed three times in sterile distilled water (SDW) to remove any disinfectant residues. After rinsing, pieces of the plant tissues at the junction of the healthy and diseased areas were dissected with a sterile scalpel and homogenized in sterile bags for homogenization of samples (Bioreba) in 3 ml of SDW. A series of decimal dilutions were made in SDW, from the obtained homogenizates, and aliquots of 0.1 ml of 10⁻¹, 10⁻² and 10⁻³ dilutions were streaked onto Petri dishes containing Tryptic Soy Agar (TSA) (Sigma Aldrich Ltd.). The bacterial suspension was spread on the medium with a glass rod and incubated for 48 h at 27°C. The efficacy of the sterilization process was verified by plating 0.1 ml of sterile distilled water from the last rinsate on the TSA medium. The lack of colonies grown after incubation indicated effective sterilization.

From the dissected plant tissues the bacterial colonies were grown on TSA medium. For each sample, three quantitatively dominant morphotypes were isolated, and by using a series of reduction streaks, from each morphotype a pure culture strain was obtained. The cultures were Gram-stained and their purity was verified under an optical microscope. Next, the strains were identified using a Biolog Gen III system (BIOLOG Inc. Hayward, CA) according to the manufacturer's instructions. The Biolog Gen III system is a ready-made diagnostic kit containing powdered media on a 96-well plate to identify Gram-positive and Gram-negative bacteria. The Biolog Gen III test panel contained 71 carbon sources and 23 chemicals to determine the sensitivity of the isolate to be tested. The Gen III system analyzed the ability of a bacterial cell to metabolize all major classes of compounds and enabled the determination of other important physiological properties, such as functioning at a certain pH, salinity and lactic acid tolerance, reducing power and

chemical sensitivity of the examined bacterial strain. As a result of the analysis, a unique biochemical profile of 95 characteristics of the examined strain was obtained for each bacterial strain. The profile was verified against the Biolog Gen III system's database containing nearly 3,000 other biochemical profiles, including those of phytopathogenic bacteria. The algorithm, based on the differences between individual biochemical profiles, estimated the degree of kinship of the tested isolates and expressed it in special units. On this basis, the bacterium under study was identified and the names of species with the closest biochemical profile were also given (Chojniak *et al.* 2015). Tested bacterial strains were inoculated onto BUG medium (BIOLOG Inc. Hayward, CA) and incubated for 24 h at 27°C. Bacterial colonies which grew after incubation were suspended in inoculation fluid (IF-A) (BIOLOG Inc. Hayward, CA) to prepare a suspension at the manufacturer's specified bacterial concentration. An aliquot of 0.1 ml of this suspension was then applied to each well in a 96 well of Gen III plate and incubated at the temperature optimal for the tested strain, which is 27°C for most bacterial plant pathogens (Schaad *et al.* 2001). After incubation, a microplate was placed in a dedicated reader where, based on spectrophotometric measurements, the system measured the optical density (OD_{595 nm}) in each well. This biochemical profile was verified against the Biolog Gen III system database. The identification result was given in the form of the name of the bacterial species with a biochemical profile contained in the Biolog database that was closest to the profile of the isolate under study. The database v. 2.8.0. that we used contained biochemical profiles of 1568 species of aerobic bacteria, including profiles of most known bacterial plant pathogens. When necessary, a pathogenicity test was performed to confirm the pathogenic properties of the test strain. The appropriate kind of test and a host plant were selected for each sample individually. In PDC, the most commonly used test is a hypersensitivity reaction on tobacco plants, because many phytopathogenic bacteria can cause this effect. The test was performed as follows: from a 24-h (27°C) strain's pure culture grown on BUG medium (Biolog Hayward, USA), a bacterial suspension with a concentration of 10⁷ cfu · ml⁻¹ was prepared in SDW. Next, tobacco plants were infected by injecting the suspension into the bottom side of the leaf blade, under the epidermis. The positive control was the reference strain of the bacterial plant-pathogen with known properties, e.g. *Pectobacterium carotovorum*. Negative controls were plants injected with sterile distilled water instead of the bacterial suspension. A positive result of the hypersensitivity reaction was manifested in the form of necrosis, observed 48–72 h after inoculation.

Results

From the founding of the PDC until December of 2019, a total of 394 samples were tested for the presence of plant-pathogenic bacteria. From the supplied plant samples, seven functional groups of plants were distinguished based on the manner of plant use. The groups were vegetables, fruits, ornamental plants, herbs, trees, shrubs and other plants that could not be explicitly qualified into one of the groups mentioned above.

In the vegetable group, the tomato was the most frequently studied plant (185 samples = 48%). Next were: cucumber (18 samples), onion (8), cauliflower (6), broccoli and carrots (4), beetroot (8), pepper (2), lettuce (2), white cabbage (2), asparagus (2), turnip (1), radish (1), kale (1) and Chinese cabbage (1).

Among the ornamental plants, geranium (8 samples) was the most numerous, followed by chrysanthemum (5), lily (5), begonia (4), primula (3), eustoma (3), violet (3), anthurium (2), gerbera (2), aster (2), phlox (1), anchusa (1), rose (1), cyclamen (1), brunnera (1), epimedium (1), navelwort (1), periwinkle (1), knotweed (1), anemone (1), clove (1), saxifrage (1), magnolia (1), surfinia (1), hellebore (1), bedbug (1), catnip (1), tiarella (1), craving (1) and anafalis (1).

The most frequently studied fruits were strawberry (6 samples) and blueberry (6) as well as raspberry (5), watermelon (3), apple tree (1) and Kamchatka berry (1).

Among the herbs, the largest number of samples was recorded for St. John's wort (3), sage (2), lavender (1) and basil (1).

The following trees and shrubs were examined: fruit tree rootstocks (3 samples), spruce (2), birch (1), willow (1), catalpa (1), boxwood (1), thuja (1) and juniper (1).

The most frequently examined agricultural plants included: sugar beet (6 samples), potato (5), pea (1), rape (1), soybean (1), corn (1) and barley (1).

In the last group of plants, not eligible for any of the above groups, the following were tested: echinodorus (aquarium plant) (2 samples), sedge (1), reed (1), peach (1), ivy (1), tobacco (1) and fungi (*Agaricus bisporus*) (1). The plant species most frequently studied in the PDC are listed in Table 1.

Since tomato was the most frequently tested plant in PDC, we investigated the percentage of the tested samples (a total of 185) per voivodeship. The region with the largest percent was Greater Poland (45% of tested tomato samples), next Lower Silesia (27%) and Masovian voivodeship (Fig. 1).

During the tests, using the Biolog Gen III system, not only was the presence or absence of a bacterial pathogen in the sample determined, but also the species identity of each tested strain was assessed, if there

Table 1. Plant species most frequently examined in the Plant Disease Clinic

Species of the tested plant	Quantity of tested samples
Tomato (<i>Solanum lycopersicum</i> L.)	185
Cucumber (<i>Cucumis sativus</i> L.)	18
Beetroot (<i>Beta vulgaris</i> L.)	8
Onion (<i>Allium cepa</i> L.)	8
Blueberry (<i>Vaccinium</i> L.)	6
Cauliflower (<i>Brassica oleracea</i> L. var. <i>botrytis</i> L.)	6
Pelargonium (<i>Pelargonium</i> L'Hér.)	6
Strawberry (<i>Fragaria ananassa</i> Duchesne)	6
Chrysanthemum (<i>Dendranthema</i> Des Moul)	5
Lily (<i>Lilium</i> L.)	5
Raspberry (<i>Rubus</i> L.)	5
Potato (<i>Solanum tuberosum</i> L.)	5
Carrot (<i>Daucus carota</i> L.)	4
Broccoli (<i>Brassica oleracea</i> L. var. <i>italica</i> Plenck)	4

**Fig. 1.** The percentage (%) of tested tomato samples per voivodeship

was a matching reference in the Biolog's database. In this way, all the pathogenic bacterial strains and most of the accompanying endophytic strains found in plant tissues were identified biochemically. These data were summarized in Tables 2–7 and aligned with the data on the number of identified bacterial species, the

number of identification cases and with information as to whether a given strain is a plant pathogen or not.

Both detecting the presence of fungi and viruses in plant samples, and the presence of phytopathogenic bacteria are basic objectives of the Clinic's activity. The data collected in the years 2013–2019 made it possible

to extract a list of 26 species of most commonly occurring plant pathogenic bacteria. These pathogens were detected in the following species of plants with a given frequency:

- *Clavibacter michiganensis* (14 detections on tomato),
- *Pseudomonas syringae* (17 detections on tomato, lily, tiarella and strawberry),
- *Pseudomonas viridilivida* (17 detections on tomato, cauliflower, chrysanthemum, eustoma, omphalodes, surfinia, strawberry and basil),
- *Pectobacterium carotovorum* (12 detections on tomato, cucumber, pepper, turnip and primula),
- *Pantoea agglomerans* (32 detections on tomato, chrysanthemum, lily, geranium, anchusa, cyclamen, brunnera, periwinkle, saxifraga, catnip, raspberry, apple, watermelon, blueberry, carrot, willow, catalpa, boxwood, thuja, juniper, potato, maize, carex, tobacco and fruit tree rootstocks),
- *Rhizobium radiobacter* (12 detections on tomato, cucumber, violet, anthurium, brunnera and carex),
- *Pantoea ananatis* (8 detections on tomato and raspberry),
- *Pseudomonas tolaasii* (15 detections on tomato, carrot, asparagus, Chinese cabbage, eustoma, water pepper, anemone, strawberry, soya and champignon),
- *Pseudomonas marginalis* (9 detections on tomato, asparagus, white cabbage, surfinia and strawberry),
- *Curtobacterium flaccumfaciens* (8 detections on tomato, geranium, blueberry, catalpa, white beet and ivy),
- *Pseudomonas cichorii* (7 detections on tomato, primula, violet and potato),
- *Pseudomonas corrugata* (3 detections on tomato),
- *Xanthomonas axonopodis* (2 detections on tomato),
- *Erwinia rhapontici* (4 detections on tomato, boxwood, thuja and pea),
- *Pantoea cypripedii* (3 detections on tomato and geranium),
- *Pectobacterium atrosepticum* (1 detection on tomato),
- *Pseudomonas asplenii* (1 detection on tomato),
- *Pseudomonas caricapapayae* (5 detections on tomato, cauliflower, anchusa and rape),
- *Pseudomonas flavescens* (4 detections on tomato, periwinkle and sedge),
- *Xanthomonas hortorum* (5 detections on tomato, white cabbage, geranium, catnip and sage),
- *Acidovorax avenae* (1 detection on cucumber),
- *Burkholderia gladioli* (1 detection on onion),
- *Xanthomonas arboricola* (1 detection on white cabbage),
- *Xanthomonas euvesicatoria* (1 detection on tiarella),
- *Xanthomonas oryzae* (1 detection on sedge),
- *Lelliottia amnigena* (7 detections on fruit tree rootstocks and white beet),
- *Kosakonia cowanii* (11 detections on soya and draacaena).

The most frequently identified plant pathogens and their percentage in total samples tested is presented in Figure 2.

Table 4. Bacterial species isolated from fruit plants and identified with the Biolog Gen III system (v. 2.8.0)

No.	Tested plant	Identified	Quantity of identification	Plant pathogen (yes/no)

		<i>Pseudomonas fulva</i>	1	no
		<i>Stenotrophomonas maltophilia</i>	1	no
		<i>Enterobacter amnigenus</i>	1	no
		<i>Bacillus gibsonii</i> / <i>murimartini</i>	1	no
4.	Watermelon (<i>Citrullus lanatus</i>)	<i>Pseudomonas putida</i>	5	no
		<i>Siccibacter turicensis</i>	2	no
		<i>Acinetobacter lwoffii</i>	1	no
		<i>Pantoea agglomerans</i>	1	yes
		<i>Enterobacter aerogenes</i> (<i>Klebsiella mobilis</i>)	1	no
		<i>Acinetobacter guillouiae</i>	1	no
		<i>Microbacterium maritypicum</i>	1	no
5.	Apple (<i>Malus domestica</i>)	<i>Enterobacter amnigenus</i>	3	no
		<i>Pantoea agglomerans</i>	3	yes
6.	Kamchatka blueberry (<i>Lonicera caerulea</i>)	<i>Bacillus marisflavi</i>	1	no

Additionally, the percentage of bacterial pathogen detections for the most frequently studied plant species is presented below for tomato (Table 8) and other plants (Table 9).

Discussion

Professional plant breeders and producers make up the majority of the Clinic's clients. The other clients are owners of individual horticultural and agricultural

farms. Orders from individual private persons are a minority. Following this specific client's profile, it is understandable that a relationship between tested plant species and the period of year is observed. For example, most chrysanthemums to be tested are commissioned in the autumn, before All Saints' Day. Ornamental plants are sent for examination mainly in the spring and summer, which coincides with their flowering period. Tomatoes are commissioned for testing throughout most of the year, but mainly in the summer. In the autumn-winter period, tests for detecting the occurrence of pathogenic bacteria for plants are usually

<i>Xanthomonas hortorum</i>	1	0.54

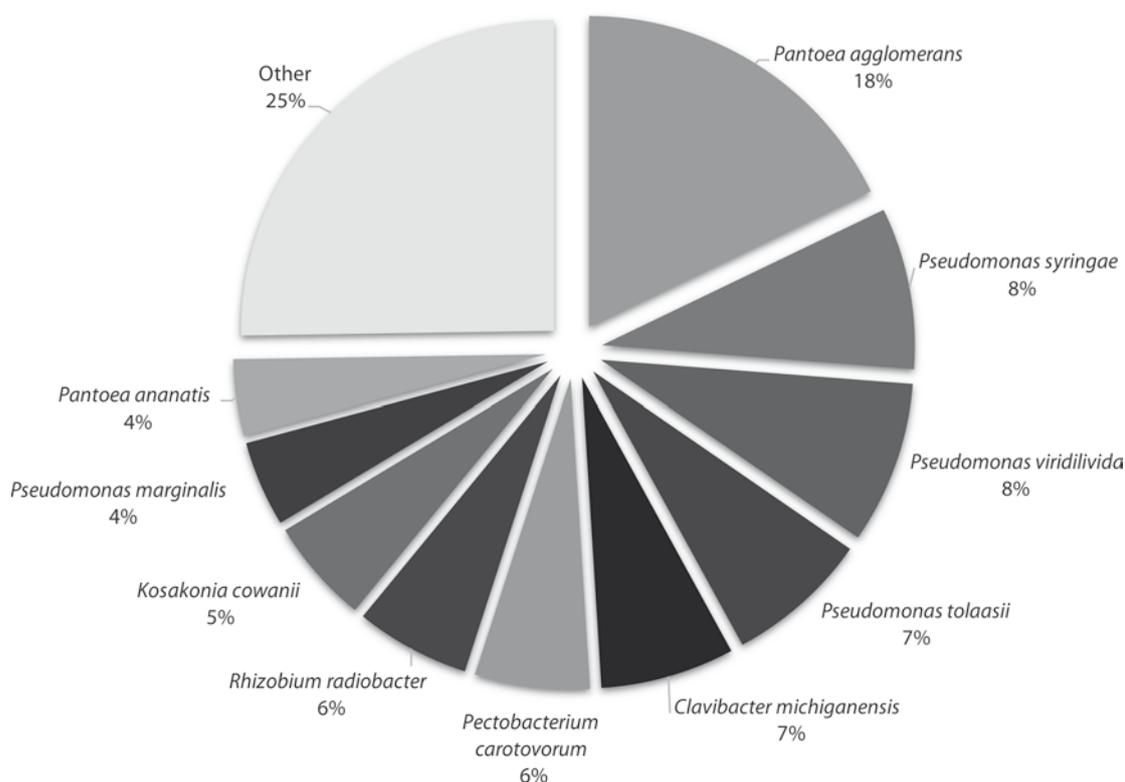

Fig. 2. The percentage of the 10 most frequently identified plant pathogens in a total number of 202 identifications of pathogenic bacterial strains isolated from 394 plant samples tested in the Plant Disease Clinic in 2013–2019

commissioned by producers growing their crops in greenhouses. The location distribution of the tested tomato samples presented in Figure 2 was affected by the proximity to the clinic. For this reason Greater Poland was most represented (45%). It also reflects the distribution of tomato growers in Poland, where in fact the three most frequently represented voivodeships are the main regions of tomato production (Fig. 2).

The scope of bacterial plant pathogens detected in the PDC (Fig. 1, Tables 2–3) is consistent with the list of the 10 most dangerous bacterial plant pathogens published by Mansfield *et al.* (2012). This list includes, starting with the most damaging crops: *Pseudomonas syringae* (all pathovars), *Ralstonia solanacearum*, *Agrobacterium tumefaciens*, *Xanthomonas oryzae* pv. *oryzae*, *Xanthomonas campestris* (all pathovars), *Xanthomonas axonopodis* pv. *manihotis*, *Erwinia amylovora*, *Xylella fastidiosa*, *Dickeya dadantii* (and *solani*) and *Pectobacterium carotovorum* (and *P. atrosepticum*) (Mansfield *et al.* 2012). Among the 10 most dangerous bacterial plant pathogens, four of them were found in the clinic: *Pseudomonas syringae*, *Pectobacterium carotovorum*, *Xanthomonas axonopodis* and *Pectobacterium atrosepticum* (Table 2), which clearly shows that these pathogens are still a real threat for crops. In the tomato samples themselves, the presence of four of the listed pathogens was also noted (Table 2). Moreover, the presence of 16 other plant pathogen species was detected

in the tomato samples under study, of which *Clavibacter michiganensis* was most frequently represented (Table 2). Also, the bacterial species causing the most common tomato diseases in Poland were observed, including *Pseudomonas syringae* pv. *tomato* (Buell *et al.* 2003; Zhao *et al.* 2003), bacterial leaf spot caused by *Xanthomonas campestris* pv. *vesicatoria* (Jones 1986; Ciardi *et al.* 2000), bacterial tomato cancer (*Clavibacter michiganensis* subsp. *michiganensis*) (Gartemann *et al.* 2003), pith necrosis (*Pseudomonas corrugata*) (Scarlett and Fletcher 1978; Lukezic 1979), bacterial wet rot (*Pectobacterium carotovorum*) (Daami-Remadi 2007; Ahmed *et al.* 2017) and crazy roots disease (*Rhizobium radiobacter*) (Sawada and Azegami 2014; Bosmans *et al.* 2017). The remaining bacterial species listed in Table 2 and identified in tomato samples are mentioned in the literature as pathogens of other crop plants and for champignon (*Agaricus bisporus*) in the case of *Pseudomonas tolaasii*. To our knowledge, previously, these bacteria had never been recorded as occurring on tomato. This is valuable information because it enriches our knowledge about the potential range of hosts of each bacterium and the range of pathogens for tomato. For the first time, we found the presence of the following bacterial species on tomato plants: *Pseudomonas viridilivida*, *Pantoea agglomerans*, *Pantoea ananatis*, *Pseudomonas tolaasii*, *Curtobacterium flaccumfaciens*, *Pseudomonas marginalis*, *Pseudomonas cichorii*, and

Table 9. The number of registered identifications of a plant pathogen per number of samples: cucumber, white beet, onion and blueberry

Plant host and pathogenic bacteria identified	Identification quantity	% of samples
Cucumber (18 samples)		
<i>Acidovorax avenae</i>	1	5.56
<i>Pectobacterium carotovorum</i>	1	5.56
<i>Rhizobium radiobacter</i>	1	5.56
Sugar beet (8 samples)		
<i>Pseudomonas marginalis</i>	2	25.00
Onion (8 samples)		
<i>Burkholderia gladioli</i>	2	25.00
Blueberry (6 samples)		
<i>Curtobacterium flaccumfaciens</i>	1	16.67
<i>Pantoea agglomerans</i>	2	33.33

Erwinia rhapontici. However, since these results were confirmed using only the Biolog Gen III system, this information needs to be confirmed by further testing using another method, e.g. a molecular method, like 16S rDNA sequencing.

In the case of cucumber, sugar beet, onion and blueberry, the observed profile of pathogenic bacteria was slightly different, because from the list of the 10 most dangerous bacterial pathogens only the presence of *Pectobacterium carotovorum* and *Rhizobium radiobacter* on cucumber was noted. Other pathogenic species identified were: *Acidovorax avenae*, *Pseudomonas marginalis*, *Burkholderia gladioli*, *Curtobacterium flaccumfaciens* and *Pantoea agglomerans*. These are known plant pathogens, however they occur much less frequently and with less economic importance.

During the research, in addition to data on the occurrence of pathogenic bacteria on plants, the occurrence of accompanying, cultivable, endophytic bacteria in particular plant species was also recorded.

This information can be of great importance because it gives insight into the microbiome composition of multiple plant species. The identified bacteria are the most abundant strains grown on TSA medium after isolation from crude plant homogenate. Therefore, it needs to be assumed that those strains are the most likely to be a part of the microbiome of a tested plant. However, comparing a list of bacterial species included in tomato microbiome developed by other authors (Ottesen *et al.* 2013; Tian *et al.* 2017) with a list of bacterial species identified in tomato tissue samples examined in the Plant Disease Clinic in 2013–2019, significant differences can be observed. The number of cultivable bacterial species grown from the tomato tissues in the PDC laboratory is significantly higher than that found in the literature data (Table 10). A potential explanation for these differences may be the fact that a sample of tissue from the junction of healthy and diseased tissues is routinely taken for examination at the Clinic, which is dictated by the rules of proper conduct in

Table 10. Comparison of the species composition of healthy tomato microbiome with a list of bacterial species isolated from tomato plant tissues examined in the Plant Disease Clinic in 2013–2019

Healthy tomato microbiome according to literature	Bacterial species identified in tomato tissue samples tested in Plant Disease Clinic

Healthy tomato microbiome according to literature	Bacterial species identified in tomato tissue samples tested in Plant Disease Clinic
<u>Phylum Rhizobiales:</u>	<i>Pantoea agglomerans</i>
Candidatus <i>Rhizobium massiliae</i>	<i>Rhizobium radiobacter</i>
<i>Rhizobium pusense</i>	<i>Pseudomonas aeruginosa</i>
<u>Phylum Enterobacteriales</u>	<i>Ralstonia pickettii</i>
<i>Enterobacter ludwigii</i>	<i>Serratia liquefaciens / grimesii</i>
<i>Enterobacter mori</i>	<i>Stenotrophomonas maltophilia</i>
<u>Phylum Pseudomonales:</u>	<i>Bacillus pumilus / safensis</i>
<i>Pseudomonas guariconensis</i>	<i>Klebsiella oxytoca</i>
<i>Pseudomonas mohnii</i>	<i>Pantoea ananatis</i>
<i>Pseudomonas plecoglossicida</i>	<i>Pseudomonas fluorescens</i>
<u>Phylum Xanthomonadales:</u>	<i>Pseudomonas plecoglossicida</i>
<i>Stenotrophomonas rhizophila</i>	<i>Pseudomonas tolaasii</i>
(Ottesen <i>et al.</i> 2013)	<i>Bacillus marisflavi</i>
Genera: <i>Pseudomonas</i> , <i>Micrococcineae</i> ,	<i>Brachybacterium alimentarium</i>
<i>Xanthomonas</i> , <i>Methylobacterium</i> ,	<i>Chryseobacterium culicis</i>
<i>Rhizobium</i> , <i>Sphingomonas</i>	<i>Empedobacter brevis</i>
	<i>Escherichia vulneris</i>
	<i>Pseudomonas marginalis</i>
	<i>Acinetobacter guillouiae</i>
	<i>Brachybacterium phenoliresistens</i>
	<i>Burkholderia pyrrocinia / cepacia</i>
	<i>Curtobacterium flaccumfaciens</i>
	<i>Enterobacter cancerogenus</i>
	<i>Microbacterium saperdae</i>
	<i>Pantoea eucrina</i>
	<i>Providencia alcalifaciens</i>
	<i>Pseudomonas alcaligenes</i>
	<i>Pseudomonas cichorii</i>
	<i>Pseudomonas corrugata</i>
	<i>Serratia rubidaea</i>
	<i>Sphingobacterium multivorum</i>
	<i>Brevibacterium epidermidis</i>
	<i>Enterobacter cloacae</i>
	<i>Acinetobacter baumannii / pittii</i>
	<i>Acinetobacter gyllenbergii</i>
	<i>Aeromonas caviae</i>
	<i>Arthrobacter globiformis</i>
	<i>Bacillus oleronius</i>
	<i>Bacillus ruris</i>
	<i>Brachybacterium rhamnosum</i>
	<i>Brevibacterium casei</i>
	<i>Clavibacter michiganensis</i> subsp. <i>michiganensis</i>
	<i>Enterobacter aerogenes</i> (<i>Klebsiella mobilis</i>)
	<i>Enterobacter nimipressuralis</i>
	<i>Exiguobacterium undae</i>
	<i>Klebsiella variicola</i>
	<i>Kluyvera intermedia</i>
	<i>Paenibacillus xylanilyticus</i>
	<i>Raoultella planticola / ornithinolytica</i>
	<i>Sphingomonas paucimobilis</i>
	<i>Staphylococcus epidermidis</i>
	<i>Staphylococcus pasteurii</i>
	<i>Staphylococcus sciuri</i> subsp. <i>sciuri</i>
	<i>Staphylococcus warneri</i>
	<i>Tetragenococcus halophilus</i> subsp. <i>halophilus</i>
	<i>Xanthomonas axonopodis</i>

Table 10. Comparison of the species composition of healthy tomato microbiome with a list of bacterial species isolated from tomato plant tissues examined in the Plant Disease Clinic in 2013–2019 – continuation

Healthy tomato microbiome according to literature	Bacterial species identified in tomato tissue samples tested in Plant Disease Clinic
	<i>Bacillus atrophaeus / subtilis</i>
	<i>Acinetobacter beijerinckii</i>
	<i>Acinetobacter genomospecies</i>
	<i>Acinetobacter johnsonii</i>
	<i>Aeromonas hydrophila</i> subsp. <i>anaerogenes</i>
	<i>Aeromonas hydrophila</i> subsp. <i>hydrophila</i>
	<i>Arthrobacter histidinolorovans</i>
	<i>Arthrobacter woluwensis</i>
	<i>Bacillus amyloliquefaciens</i> subsp. <i>amyloliquefaciens</i>
	<i>Bacillus indicus</i>
	<i>Bacillus nealsonii</i>
	<i>Bacillus safensis</i>
	<i>Bordetella trematum</i>
	<i>Brevibacterium sanguinis</i>
	<i>Burkholderia ambifaria / cepacia</i>
	<i>Cedecea neteri</i>
	<i>Chryseobacterium balustinum</i>
	<i>Chryseobacterium scophthalmum</i>
	<i>Chryseobacterium taichungense</i>
	<i>Citrobacter freundii</i>
	<i>Citrobacter sedlakii</i>
	<i>Citrobacter werkmanii</i>
	<i>Clavibacter michiganensis</i> subsp. <i>tessellarius</i>
	<i>Comamonas testosteroni</i>
	<i>Corynebacterium kroppenstedtii</i>
	<i>Cupriavidus gilardii</i>
	<i>Cupriavidus pauculus</i>
	<i>Curtobacterium flaccumfaciens</i> pv. <i>oortii</i>
	<i>Curtobacterium luteum</i>
	<i>Dermacoccus nishinomiyaensis</i>
	<i>Enterobacter amnigenus</i>
	<i>Erwinia rhapontici</i>
	<i>Flavobacterium johnsoniae</i>
	<i>Janibacter hoylei / anophelis</i>
	<i>Jonesia denitrificans</i>
	<i>Kluyvera ascorbata</i>
	<i>Kocuria varians</i>
	<i>Leclercia adecarboxylata</i>
	<i>Macrococcus brunensis</i>
	<i>Microbacterium arborescens</i>
	<i>Microbacterium flavescens</i>
	<i>Microbacterium testaceum</i>
	<i>Mirobacterium maritypicum</i>
	<i>Moraxella lincolnii</i>
	<i>Novosphingobium capsulatum</i>
	<i>Ochrobactrum anthropi</i>
	<i>Ochrobactrum grignonense</i>
	<i>Paenibacillus alkaliterrae</i>
	<i>Paenibacillus anaericanus</i>
	<i>Paenibacillus provencensis</i>
	<i>Paenibacillus soli</i>
	<i>Paenibacillus stellifer</i>
	<i>Paenibacillus taichungensis / pabuli</i>
	<i>Paenibacillus popiliae</i>
	<i>Pantoea ananatis</i> pv. <i>ananatis</i>
	<i>Pantoea cypripedii</i>

Table 10. Comparison of the species composition of healthy tomato microbiome with a list of bacterial species isolated from tomato plant tissues examined in the Plant Disease Clinic in 2013–2019 – continuation

Healthy tomato microbiome according to literature	Bacterial species identified in tomato tissue samples tested in Plant Disease Clinic
	<i>Paraburkholderia caryophylli</i>
	<i>Pectobacterium atrosepticum</i>
	<i>Pediococcus acidilactici</i>
	<i>Providencia stuartii</i>
	<i>Pseudomonas asplenii</i>
	<i>Pseudomonas caricapapayae</i>
	<i>Pseudomonas flavescens</i>
	<i>Pseudomonas fragi</i>
	<i>Pseudomonas fulva</i>
	<i>Pseudomonas nitroreducens</i>
	<i>Pseudomonas oleovorans</i> subsp. <i>oleovorans</i>
	<i>Pseudomonas stutzeri</i>
	<i>Pseudomonas synxantha</i>
	<i>Pseudomonas syringae</i>
	<i>Pseudomonas syringae</i> pv. <i>daphniphylli</i>
	<i>Pseudomonas syringae</i> pv. <i>helianthi</i>
	<i>Pseudomonas syringae</i> pv. <i>maculicola</i>
	<i>Rathayibacter rathayi</i>
	<i>Rothia amarae</i>
	<i>Staphylococcus capitis</i> subsp. <i>urealyticus</i>
	<i>Staphylococcus cohnii</i> subsp. <i>cohnii</i>
	<i>Staphylococcus intermedius</i>
	<i>Staphylococcus sciuri</i> subsp. <i>carnaticus</i>
	<i>Staphylococcus xylosus</i>
	<i>Streptococcus oralis</i>
	<i>Tatumella punctata</i>
	<i>Xanthomonas hortorum</i> pv. <i>pelargonii</i>
	<i>Yersinia intermedia</i>

classical microbiology. Hence, some bacterial species may in fact, not be a part of a healthy tomato plant microbiome. Nevertheless, these data may give insight into the dynamics of disease developmental processes.

In summary, the data presented above represents an approximation of the current biodiversity state of the main crops in Poland, along with the most common bacterial symbionts and pathogens. Also, the data presented in the supplement constitute a good basis for determining the profile of bacterial diseases of agricultural and ornamental plants in Poland. This information is extremely valuable primarily for phytosanitary services, e.g. for the development of control plans and for further research because it includes new data about plant microbiomes.
