Abstract: A total of nineteen parasitoid species were recorded from agromyzid leafminers in some sites of Middle Anatolia. These species were: *Diglyphus iiseae* (Walker), *D. pachyneurus* Graham, *D. crassinervis* Erdös, *D. pusztensis* (Erdös&Novicky), *D. begini* (Ashmead), *Baryscapus* sp., *Hemiptarsenus zilahisebessi* Erdös, *Pnigalio soemius* (Walker), *Neochrysocharis formosa* (Westwood), *N. clara* Szelenyi, *N. arvensis* Graham, *N. chlorogaster* (Erdös), *Chrysocharis pentheus* (Walker), *C. ptherne* (Walker), *C. pubicornis* (Zetterstedt), *C. viridis* (Nees), *Pediobius metallicus* (Walker) (Eulophidae), *Epicerus panyas* (Walker) (Tetracampidae), and *Merismus* sp. (Pteromalidae). Among the parasitoids reared, *Diglyphus begini* and *Chrysocharis viridis* have been for the first time found in Turkey, *D. crassinervis*, *H. zilahisebessi*, and *N. clara* and *E. panyas* were recorded from *Chromatomyia horticola* and *P. soemius* was recorded from *Liriomyza strigata* were recorded for the first time.

Key words: Chalcidoidea, leafminers, parasitoids, Turkey

INTRODUCTION

Leafminers are among the most serious polyphagous insect pests of vegetable and ornamental plants in the world (Spencer 1973). The adults are commonly found on vegetation, whereas the most larvae are leafminers. Considerable damage is caused by larvae. The larvae feed within the leaves of the host plant and this feeding can severely reduce yields and/or kill the plants at high fly density (Spencer and Steyskal 1986). Many factors induce leafminer outbreaks, but the loss of natural enemies due to widespread use of insecticides is one of the most important. Agromyzid leafminers are known to have rich natural enemy communities. Parasitoids are the major group of natural enemies of leafminer and they have played a very important role in leafminer suppression in natural ecosystems or cultivated areas with reduced insecticide use (Johnson *et al.* 1980). Leafminers parasitoids have been intensively and extensively investigated and evaluated in many countries with more than 100 species reported, and several, such as *Diglyphus begini* and *Dacnusa sibirica*, were successfully used as biological control agents in commercial greenhouses planted with vegetables and ornamental plants, especially tomato and chrysanthemum in Europe and North America (Chen *et al.* 2003). Leafminers have also become a serious problem in vegetable production in Turkey in recent years (Uygun *et al.* 2003; Çikman *et al.* 2006; Uygun *et al.*1995; Gençer 2004, 2005). However, no systematic or comprehensive field investigation has been carried out in sites around Sivas to assess the occurrence of leafminers and their parasitoids in cultivated vegetable and uncultivated plants. Thus, the objective of this study was to identify species of agromyzid parasitoids and their host plants in the Middle Anatolia.

MATERIALS AND METHODS

Leafminer-infested leaves from Sivas, Kayseri, Tokat, Malatya and Giresun were collected from March 2004 to October 2005. Leafminer-infested leaves were taken to the laboratory for the emergence of pests and parasitoids. The laboratory temperature was approximately 25–30°C and the relative humidity was between 60 and 70%. Samples (leafminer-infested) were cleared of other insects and residues and categorized according to plant species. All leaves were carefully examined under microscope to count the number of mines where leafminer larvae were present. Samples were placed in a small glass vials and then closed with a cotton ball covered with muslin. They were daily checked for the emergence of leafminers and parasitoids and relevant notes were made. After the completion of emergence, all reared pest and parasitoid specimens were identified.

All the parasitoids were identified by the author using the relevant literature (Hansson 1985, 1990; Graham 1959,

Neochrysocharis clara, Epiclerus panyas from Turkey. Data of identifications of 611 reared parasitoid were as follows were identified. (Table 1). Distribution of quantitative reared from the leaves infested by nearly every plant. The reared leafminer species and their composition and proportionate contribution to overall parasitoids and host plants (Parella 1987). Just the same, parasitoid species impact of climate and their distinct preferences for host plants are given in table 1. A total of sixteen parasitoid species were identified by Dr. E. Dönmez (Cumhuriyet University, Department of Biology) and the plants were identified by Dr. H.S. Civelek (Muğla University, Department of Biology). The specimens were kept in the collection of Department of Biology, Cumhuriyet University, Sivas, Turkey.

RESULTS
Host species composition
Six leafminers species; L. cicerina, L. strigata, L. trifoli, Liriomyza sp., Phytomyza lappae and Chromatomyia horticola were reared from the collected leaves. The most common agromyzid species was Chromatomyia horticola reared from nearly every plant. The reared leafminer species and their host plants are given in table 1. Chromatomyia horticola and L. cicerina were present mostly from May to August, the other species from June to July. Although both C. horticola and L. cicerina appeared on host plants initially in May, in general C. horticola occurred earlier than L. cicerina.

Parasitoid species complex
A total of 611 parasitoid adults were reared from collected leafminer and 19 parasitoid species of three families were identified. (Table 1). Distribution of quantitative data of identifications of 611 reared parasitoid were as follows; Diglyphus isae 367, D. pachyneurus 14, D. crassinervis 9, D. pusstenzis 1, D. begini 1, Baryscapus sp. 1, Hemiptarsenus zilahisebessi 2, Pnigalio soemius 1, Neochrysocharis formosa 8, N. clara 27, N. arvensis 5, N. chlorogaster 2, Chrysocharis penteus 38, C. pnyren 2, C. pubicornis 39, C. viridis 1, Pediobius metallicus 89, Epicerus panyas 3, and Merismus sp. 1. Among them Diglyphus isae, Pediobius metallicus, Chrysocharis pubicornis and C. penteus were recorded as the most common parasitoids. In addition, Diglyphus begini and Chrysocharis viridis have been newly recorded in Turkey. Diglyphus crassinervis, Hemiptarsenus zilahisebessi, Neochrysocharis clara, Epicerus panyas from C. horticola and Pnigalio soemius from L. strigata were recorded for the first time.

Host-parasitoid relationship
Parasitoid complex of the 6 host species were remarkably similar. A total of sixteen parasitoid species were reared from the leaves infested by C. horticola. Among them D. isae was the most abundant species accounting for 26.19–68.86% of all reared parasitoid adults.

DISCUSSION
In recent years, the population size of pest species has increased dramatically and have been recognized as a very important pest group in Turkey (Uygun et al. 1995). The occurrence and relative abundance of leafminers associated with seasons and host plants may reflect the impact of climate and their distinct preferences for host plants (Parella 1987). Just the same, parasitoid species composition and proportionate contribution to overall parasitoid abundance vary in different areas and seasons (Darvas et al. 1999; Chen et al. 2003). This study showed that under natural conditions the leafminers in Middle Anatolia were attacked by a diverse parasitoid complex. However, most of species found were not specific to these leafminers. In addition, parasitoids D. crassinervis, H. zilahisebessi, N. clara, E. panyas from C. horticola and P. soemius from L. strigata were recorded for the first time.

Diglyphus isae, P. metallicus, C. pubicornis and C. pentheus are considered to be important parasitoids of agromyzid flies. A rate of emergence higher than 10% among all parasitoids are reported to be significant and they are considered to be potential biological control agents (Murphy and LaSalle 1999). These parasitoids deserve further study with respect to their biology and ecology. A relative parasitism level in the field as indicated in this study may suggest that parasitoids could be an important mortality factor in the population dynamics of leafminer population. However, in addition to high parasitoids’ levels, several important factors have to be take into account in order to increase success rates in biological control programs. These factors include distribution, climate and host specificity. These results suggest that the biodiversity of both parasitoids and host plants of leafminer contribute to balance of leafminer population on crops.
